

STAT 301 In-class Activity No. 11

Consider the “wage” dataset again. We wish to choose a “best” set of predictors in a logistic regression model with “wage being above/below average” as the response and **all other variables** in the dataset as predictors (called full model).

(1) Choose the “best” set of predictors using the stepwise variable selection method “step()”. What predictors are selected? Are they all significant?

(2) We wish to test if the selected model in (1) is significantly better than the “full model” with all predictors. Perform the deviance test using R function “anova()”.
