

# STAT 301 In-class Activity No. 12

Consider the “wage” dataset again. We wish to choose a “best” linear regression model with “wage” as the response and other variables in the dataset as predictors. Consider R package **glmnet** and use the LASSO method for choosing the “best” set of predictors.

- (1) What are the set of predictors selected based on the penalty value  $\lambda$  chosen by the cross-validation method?
- (2) Are the set of predictors chosen in (1) the same as the ones selected by the “stepwise” method? Why?
