

STAT 301 In-class Activity No. 7

Consider the “wage” dataset again. Last time, we defined a new response y for individual i as follows: $y_i = 1$ if individual i ’s wage is above average and $y_i = 0$ otherwise. Fit a logistic regression model with the new response and predictors EDUCATION and SEX.

- (1) Are EDUCATION and SEX associated with an individual’s wage being above/below average?
- (2) For a female with 16 years of education, what is the estimated probability that her wage is above average?
